# 0.1 Introduction

#### **Problem 1.1 Solution**

We let the derivative of *error function E* with respect to vector  $\mathbf{w}$  equals to  $\mathbf{0}$ , (i.e.  $\frac{\partial E}{\partial \mathbf{w}} = 0$ ), and this will be the solution of  $\mathbf{w} = \{w_i\}$  which minimizes *error function E*. To solve this problem, we will calculate the derivative of E with respect to every  $w_i$ , and let them equal to 0 instead. Based on (1.1) and (1.2) we can obtain:

$$\frac{\partial E}{\partial w_{i}} = \sum_{n=1}^{N} \{y(x_{n}, \mathbf{w}) - t_{n}\} x_{n}^{i} = 0$$

$$= > \sum_{n=1}^{N} y(x_{n}, \mathbf{w}) x_{n}^{i} = \sum_{n=1}^{N} x_{n}^{i} t_{n}$$

$$= > \sum_{n=1}^{N} (\sum_{j=0}^{M} w_{j} x_{n}^{j}) x_{n}^{i} = \sum_{n=1}^{N} x_{n}^{i} t_{n}$$

$$= > \sum_{n=1}^{N} \sum_{j=0}^{M} w_{j} x_{n}^{(j+i)} = \sum_{n=1}^{N} x_{n}^{i} t_{n}$$

$$= > \sum_{j=0}^{M} \sum_{n=1}^{N} x_{n}^{(j+i)} w_{j} = \sum_{n=1}^{N} x_{n}^{i} t_{n}$$

If we denote  $A_{ij} = \sum_{n=1}^{N} x_n^{i+j}$  and  $T_i = \sum_{n=1}^{N} x_n^i t_n$ , the equation above can be written exactly as (1.222), Therefore the problem is solved.

## **Problem 1.2 Solution**

This problem is similar to Prob.1.1, and the only difference is the last term on the right side of (1.4), the penalty term. So we will do the same thing as in Prob.1.1:

$$\frac{\partial E}{\partial w_{i}} = \sum_{n=1}^{N} \{y(x_{n}, \mathbf{w}) - t_{n}\} x_{n}^{i} + \lambda w_{i} = 0$$

$$= > \sum_{j=0}^{M} \sum_{n=1}^{N} x_{n}^{(j+i)} w_{j} + \lambda w_{i} = \sum_{n=1}^{N} x_{n}^{i} t_{n}$$

$$= > \sum_{j=0}^{M} \{\sum_{n=1}^{N} x_{n}^{(j+i)} + \delta_{ji} \lambda\} w_{j} = \sum_{n=1}^{N} x_{n}^{i} t_{n}$$

where

$$\delta_{ji} \begin{cases} 0 & j \neq i \\ 1 & j = i \end{cases}$$

#### **Problem 1.3 Solution**

This problem can be solved by *Bayes' theorem*. The probability of selecting an apple P(a):

$$P(a) = P(a|r)P(r) + P(a|b)P(b) + P(a|g)P(g) = \frac{3}{10} \times 0.2 + \frac{1}{2} \times 0.2 + \frac{3}{10} \times 0.6 = 0.34$$

Based on *Bayes' theorem*, the probability of an selected orange coming from the green box P(g|o):

$$P(g|o) = \frac{P(o|g)P(g)}{P(o)}$$

We calculate the probability of selecting an orange P(o) first:

$$P(o) = P(o|r)P(r) + P(o|b)P(b) + P(o|g)P(g) = \frac{4}{10} \times 0.2 + \frac{1}{2} \times 0.2 + \frac{3}{10} \times 0.6 = 0.36$$

Therefore we can get:

$$P(g|o) = \frac{P(o|g)P(g)}{P(o)} = \frac{\frac{3}{10} \times 0.6}{0.36} = 0.5$$

## **Problem 1.4 Solution**

This problem needs knowledge about *calculus*, especially about *Chain rule*. We calculate the derivative of  $P_y(y)$  with respect to y, according to (1.27):

$$\frac{dp_{y}(y)}{dy} = \frac{d(p_{x}(g(y))|g'(y)|)}{dy} = \frac{dp_{x}(g(y))}{dy}|g'(y)| + p_{x}(g(y))\frac{d|g'(y)|}{dy} \tag{*}$$

The first term in the above equation can be further simplified:

$$\frac{dp_x(g(y))}{dy}|g'(y)| = \frac{dp_x(g(y))}{dg(y)}\frac{dg(y)}{dy}|g'(y)|$$
 (\*\*)

If  $\hat{x}$  is the maximum of density over x, we can obtain :

$$\frac{dp_x(x)}{dx}\big|_{\hat{x}}=0$$

Therefore, when  $y = \hat{y}, s.t.\hat{x} = g(\hat{y})$ , the first term on the right side of (\*\*) will be 0, leading the first term in (\*) equals to 0, however because of the existence of the second term in (\*), the derivative may not equal to 0. But

when linear transformation is applied, the second term in (\*) will vanish, (e.g. x = ay + b). A simple example can be shown by :

$$p_x(x) = 2x, \quad x \in [0,1] = \hat{x} = 1$$

And given that:

$$x = sin(y)$$

Therefore,  $p_y(y) = 2\sin(y)|\cos(y)|, y \in [0, \frac{\pi}{2}],$  which can be simplified :

$$p_y(y) = \sin(2y), \quad y \in [0, \frac{\pi}{2}] \quad => \quad \hat{y} = \frac{\pi}{4}$$

However, it is quite obvious:

$$\hat{x} \neq \sin(\hat{y})$$

## **Problem 1.5 Solution**

This problem takes advantage of the property of expectation:

$$var[f] = \mathbb{E}[(f(x) - \mathbb{E}[f(x)])^{2}]$$

$$= \mathbb{E}[f(x)^{2} - 2f(x)\mathbb{E}[f(x)] + \mathbb{E}[f(x)]^{2}]$$

$$= \mathbb{E}[f(x)^{2}] - 2\mathbb{E}[f(x)]^{2} + \mathbb{E}[f(x)]^{2}$$

$$=> var[f] = \mathbb{E}[f(x)^{2}] - \mathbb{E}[f(x)]^{2}$$

## **Problem 1.6 Solution**

Based on (1.41), we only need to prove when x and y is independent,  $\mathbb{E}_{x,y}[xy] = \mathbb{E}[x]\mathbb{E}[y]$ . Because x and y is independent, we have :

$$p(x, y) = p_x(x) p_y(y)$$

Therefore:

$$\iint xyp(x,y)dxdy = \iint xyp_x(x)p_y(y)dxdy$$

$$= (\int xp_x(x)dx)(\int yp_y(y)dy)$$

$$=> \mathbb{E}_{x,y}[xy] = \mathbb{E}[x]\mathbb{E}[y]$$

## **Problem 1.7 Solution**

This problem should take advantage of *Integration by substitution*.

$$I^{2} = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} exp(-\frac{1}{2\sigma^{2}}x^{2} - \frac{1}{2\sigma^{2}}y^{2}) dx dy$$
$$= \int_{0}^{2\pi} \int_{0}^{+\infty} exp(-\frac{1}{2\sigma^{2}}r^{2}) r dr d\theta$$

Here we utilize:

$$x = r\cos\theta$$
,  $y = r\sin\theta$ 

Based on the fact:

$$\int_{0}^{+\infty} exp(-\frac{1}{2\sigma^{2}})r\,dr = -\sigma^{2}exp(-\frac{r^{2}}{2\sigma^{2}})\Big|_{0}^{+\infty} = -\sigma^{2}(0-(-1)) = \sigma^{2}$$

Therefore, I can be solved:

$$I^{2} = \int_{0}^{2\pi} \sigma^{2} d\theta = 2\pi\sigma^{2}, = > I = \sqrt{2\pi}\sigma$$

And next,we will show that Gaussian distribution  $\mathcal{N}(x|\mu,\sigma^2)$  is normalized, (i.e.  $\int_{-\infty}^{+\infty} \mathcal{N}(x|\mu,\sigma^2) dx = 1$ ):

$$\begin{split} \int_{-\infty}^{+\infty} \mathcal{N}(x \big| \mu, \sigma^2) \, dx &= \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} exp\{ -\frac{1}{2\sigma^2} (x - \mu)^2 \} \, dx \\ &= \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} exp\{ -\frac{1}{2\sigma^2} y^2 \} \, dy \quad (y = x - \mu) \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{+\infty} exp\{ -\frac{1}{2\sigma^2} y^2 \} \, dy \\ &= 1 \end{split}$$

## **Problem 1.8 Solution**

The first question will need the result of Prob.1.7:

$$\begin{split} \int_{-\infty}^{+\infty} \mathcal{N}(x|\mu,\sigma^2) x \, dx &= \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} exp\{-\frac{1}{2\sigma^2} (x-\mu)^2\} x \, dx \\ &= \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} exp\{-\frac{1}{2\sigma^2} y^2\} (y+\mu) \, dy \quad (y=x-\mu) \\ &= \mu \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} exp\{-\frac{1}{2\sigma^2} y^2\} \, dy + \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} exp\{-\frac{1}{2\sigma^2} y^2\} y \, dy \\ &= \mu + 0 = \mu \end{split}$$

The second problem has already be given hint in the description. Given that:

$$\frac{d(fg)}{dx} = f\frac{dg}{dx} + g\frac{df}{dx}$$

We differentiate both side of (1.127) with respect to  $\sigma^2$ , we will obtain :

$$\int_{-\infty}^{+\infty} (-\frac{1}{2\sigma^2} + \frac{(x-\mu)^2}{2\sigma^4}) \mathcal{N}(x|\mu,\sigma^2) dx = 0$$

Provided the fact that  $\sigma \neq 0$ , we can get:

$$\int_{-\infty}^{+\infty} (x-\mu)^2 \mathcal{N}(x\big|\mu,\sigma^2) dx = \int_{-\infty}^{+\infty} \sigma^2 \mathcal{N}(x\big|\mu,\sigma^2) dx = \sigma^2$$

So the equation above has actually proven (1.51), according to the definition:

$$var[x] = \int_{-\infty}^{+\infty} (x - \mathbb{E}[x])^2 \mathcal{N}(x|\mu, \sigma^2) dx$$

Where  $\mathbb{E}[x] = \mu$  has already been proved. Therefore :

$$var[x] = \sigma^2$$

Finally,

$$\mathbb{E}[x^2] = var[x] + \mathbb{E}[x]^2 = \sigma^2 + \mu^2$$

#### **Problem 1.9 Solution**

Here we only focus on (1.52), because (1.52) is the general form of (1.42). Based on the definition: The maximum of distribution is known as its mode and (1.52), we can obtain:

$$\frac{\partial \mathcal{N}(\mathbf{x} | \boldsymbol{\mu}, \boldsymbol{\Sigma})}{\partial \mathbf{x}} = -\frac{1}{2} [\boldsymbol{\Sigma}^{-1} + (\boldsymbol{\Sigma}^{-1})^T] (\mathbf{x} - \boldsymbol{\mu}) \mathcal{N}(\mathbf{x} | \boldsymbol{\mu}, \boldsymbol{\Sigma})$$
$$= -\boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu}) \mathcal{N}(\mathbf{x} | \boldsymbol{\mu}, \boldsymbol{\Sigma})$$

Where we take advantage of:

$$\frac{\partial \mathbf{x}^T \mathbf{A} \mathbf{x}}{\partial \mathbf{x}} = (\mathbf{A} + \mathbf{A}^T) \mathbf{x} \quad \text{and} \quad (\mathbf{\Sigma}^{-1})^T = \mathbf{\Sigma}^{-1}$$

Therefore,

only when 
$$\mathbf{x} = \boldsymbol{\mu}, \frac{\partial \mathcal{N}(\mathbf{x} | \boldsymbol{\mu}, \boldsymbol{\Sigma})}{\partial \mathbf{x}} = 0$$

Note: You may also need to calculate *Hessian Matrix* to prove that it is maximum. However, here we find that the first derivative only has one zero point. Based on the description in the problem, this point should be maximum point.

## **Problem 1.10 Solution**

We will solve this problem based on the definition of expectation, variation

and independence.

$$\mathbb{E}[x+z] = \int \int (x+z)p(x,z)dxdz$$

$$= \int \int (x+z)p(x)p(z)dxdz$$

$$= \int \int xp(x)p(z)dxdz + \int \int zp(x)p(z)dxdz$$

$$= \int (\int p(z)dz)xp(x)dx + \int (\int p(x)dx)zp(z)dz$$

$$= \int xp(x)dx + \int zp(z)dz$$

$$= \mathbb{E}[x] + \mathbb{E}[z]$$

$$\begin{aligned} var[x+z] &= \int \int (x+z-\mathbb{E}[x+z])^2 p(x,z) dx dz \\ &= \int \int \{(x+z)^2 - 2(x+z)\mathbb{E}[x+z]\} + \mathbb{E}^2[x+z]\} p(x,z) dx dz \\ &= \int \int (x+z)^2 p(x,z) dx dz - 2\mathbb{E}[x+z] \int \int (x+z) p(x,z) dx dz + \mathbb{E}^2[x+z] \\ &= \int \int (x+z)^2 p(x,z) dx dz - \mathbb{E}^2[x+z] \\ &= \int \int (x^2 + 2xz + z^2) p(x) p(z) dx dz - \mathbb{E}^2[x+z] \\ &= \int (\int p(z) dz) x^2 p(x) dx + \int \int 2xz p(x) p(z) dx dz + \int (\int p(x) dx) z^2 p(z) dz - \mathbb{E}^2[x+z] \\ &= \mathbb{E}[x^2] + \mathbb{E}[z^2] - \mathbb{E}^2[x+z] + \int \int 2xz p(x) p(z) dx dz \\ &= \mathbb{E}[x^2] + \mathbb{E}[z^2] - (\mathbb{E}[x] + \mathbb{E}[z])^2 + \int \int 2xz p(x) p(z) dx dz \\ &= \mathbb{E}[x^2] - \mathbb{E}^2[x] + \mathbb{E}[z^2] - \mathbb{E}^2[z] - 2\mathbb{E}[x]\mathbb{E}[z] + 2 \int \int xz p(x) p(z) dx dz \\ &= var[x] + var[z] - 2\mathbb{E}[x]\mathbb{E}[z] + 2(\int xp(x) dx) (\int zp(z) dz) \\ &= var[x] + var[z] \end{aligned}$$

## **Problem 1.11 Solution**

Based on prior knowledge that  $\mu_{ML}$  and  $\sigma_{ML}^2$  will decouple. We will first calculate  $\mu_{ML}$  :

$$\frac{d(\ln p(\mathbf{x} \mid \mu, \sigma^2))}{d\mu} = \frac{1}{\sigma^2} \sum_{n=1}^{N} (x_n - \mu)$$

We let:

$$\frac{d(\ln p(\mathbf{x} \, \big| \, \mu, \sigma^2))}{d\mu} = 0$$

Therefore:

$$\mu_{ML} = \frac{1}{N} \sum_{n=1}^{N} x_n$$

And because:

$$\frac{d(\ln p(\mathbf{x}|\mu,\sigma^2))}{d\sigma^2} = \frac{1}{2\sigma^4} (\sum_{n=1}^{N} (x_n - \mu)^2 - N\sigma^2)$$

We let:

$$\frac{d(\ln p(\mathbf{x} \mid \mu, \sigma^2))}{d\sigma^2} = 0$$

Therefore:

$$\sigma_{ML}^2 = \frac{1}{N} \sum_{n=1}^{N} (x_n - \mu_{ML})^2$$

## **Problem 1.12 Solution**

It is quite straightforward for  $\mathbb{E}[\mu_{ML}]$ , with the prior knowledge that  $x_n$  is i.i.d. and it also obeys Gaussian distribution  $\mathcal{N}(\mu, \sigma^2)$ .

$$\mathbb{E}[\mu_{ML}] = \mathbb{E}[\frac{1}{N}\sum_{n=1}^N x_n] = \frac{1}{N}\mathbb{E}[\sum_{n=1}^N x_n] = \mathbb{E}[x_n] = \mu$$

For  $\mathbb{E}[\sigma_{ML}^2]$ , we need to take advantage of (1.56) and what has been given in the problem :

$$\mathbb{E}[\sigma_{ML}^{2}] = \mathbb{E}\left[\frac{1}{N}\sum_{n=1}^{N}(x_{n} - \mu_{ML})^{2}\right]$$

$$= \frac{1}{N}\mathbb{E}\left[\sum_{n=1}^{N}(x_{n} - \mu_{ML})^{2}\right]$$

$$= \frac{1}{N}\mathbb{E}\left[\sum_{n=1}^{N}(x_{n}^{2} - 2x_{n}\mu_{ML} + \mu_{ML}^{2})\right]$$

$$= \frac{1}{N}\mathbb{E}\left[\sum_{n=1}^{N}x_{n}^{2}\right] - \frac{1}{N}\mathbb{E}\left[\sum_{n=1}^{N}2x_{n}\mu_{ML}\right] + \frac{1}{N}\mathbb{E}\left[\sum_{n=1}^{N}\mu_{ML}^{2}\right]$$

$$= \mu^{2} + \sigma^{2} - \frac{2}{N}\mathbb{E}\left[\sum_{n=1}^{N}x_{n}(\frac{1}{N}\sum_{n=1}^{N}x_{n})\right] + \mathbb{E}\left[\mu_{ML}^{2}\right]$$

$$= \mu^{2} + \sigma^{2} - \frac{2}{N^{2}}\mathbb{E}\left[\sum_{n=1}^{N}x_{n}(\sum_{n=1}^{N}x_{n})\right] + \mathbb{E}\left[\left(\frac{1}{N}\sum_{n=1}^{N}x_{n}\right)^{2}\right]$$

$$= \mu^{2} + \sigma^{2} - \frac{1}{N^{2}}\mathbb{E}\left[\left(\sum_{n=1}^{N}x_{n}\right)^{2}\right]$$

$$= \mu^{2} + \sigma^{2} - \frac{1}{N^{2}}\mathbb{E}\left[\left(\sum_{n=1}^{N}x_{n}\right)^{2}\right]$$

$$= \mu^{2} + \sigma^{2} - \frac{1}{N^{2}}\mathbb{E}\left[\left(\sum_{n=1}^{N}x_{n}\right)^{2}\right]$$

$$= \mu^{2} + \sigma^{2} - \frac{1}{N^{2}}[N(N\mu^{2} + \sigma^{2})]$$

Therefore we have:

$$\mathbb{E}[\sigma_{ML}^2] = (\frac{N-1}{N})\sigma^2$$

## **Problem 1.13 Solution**

This problem can be solved in the same method used in Prob.1.12:

$$\begin{split} \mathbb{E}[\sigma_{ML}^2] &= \mathbb{E}[\frac{1}{N} \sum_{n=1}^{N} (x_n - \mu)^2] \quad (\text{Because here we use } \mu \text{ to replace } \mu_{ML}) \\ &= \frac{1}{N} \mathbb{E}[\sum_{n=1}^{N} (x_n - \mu)^2] \\ &= \frac{1}{N} \mathbb{E}[\sum_{n=1}^{N} (x_n^2 - 2x_n \mu + \mu^2)] \\ &= \frac{1}{N} \mathbb{E}[\sum_{n=1}^{N} x_n^2] - \frac{1}{N} \mathbb{E}[\sum_{n=1}^{N} 2x_n \mu] + \frac{1}{N} \mathbb{E}[\sum_{n=1}^{N} \mu^2] \\ &= \mu^2 + \sigma^2 - \frac{2\mu}{N} \mathbb{E}[\sum_{n=1}^{N} x_n] + \mu^2 \\ &= \mu^2 + \sigma^2 - 2\mu^2 + \mu^2 \\ &= \sigma^2 \end{split}$$

Note: The biggest difference between Prob.1.12 and Prob.1.13 is that the mean of Gaussian Distribution is known previously (in Prob.1.13) or not (in Prob.1.12). In other words, the difference can be shown by the following equations:

$$\mathbb{E}[\mu^2] = \mu^2 \quad (\mu \text{ is determined, i.e. its } expectation \text{ is itself, also true for } \mu^2)$$

$$\mathbb{E}[\mu^2_{ML}] = \mathbb{E}[(\frac{1}{N} \sum_{n=1}^N x_n)^2] = \frac{1}{N^2} \mathbb{E}[(\sum_{n=1}^N x_n)^2] = \frac{1}{N^2} N(N\mu^2 + \sigma^2) = \mu^2 + \frac{\sigma^2}{N}$$
